X-Ray Fluorescence is defined as "The emission of characteristic "secondary" (or fluorescent) X-rays from a material that has been excited by bombarding with high-energy X-rays or gamma rays. The phenomenon is widely used for elemental analysis. How does XRF work? Characteristic X-rays are emitted from elements when their electrons make transitions between the atomic energy levels. If an electron transitions from a level with energy  $E_i$  to one with energy  $E_j$ , the emitted X-ray has energy  $E_X = E_i - E_j$ . Because each element has a unique set of atomic energy levels, it emits a unique set of X-rays which are characteristic of this element. 4p 4s. The chart below illustrates the nomenclature. It is somewhat confusing, because three distinct naming systems are used for the atomic shells.
